AN OPERATIONAL PROBLEM. A DELIBERATE BOUNDARY.

The broken inbox. Look closer. Repair precisely.

How the JOLIBEN task overview became usable again, an unsuitable repair proposal was rejected and the unresolved cause stayed visible.

THE DECISIVE POINT

338 selected tests had passed. The first candidate was nevertheless not accepted: its display would have attributed global conflicts to individual tasks.

Result of the later, bounded repair

344
selected tests
according to the report

13
isolated HTTP checks
within the reported scope

HTTP 200
Inbox through both routes
previously HTTP 500 on both

The display works again. The control boundary remains.

This display repair did not change the start or approval checks. The global history conflict remained a separate, open task.

Case: 15 October 2026. Account: 22 October; English edition: 23 October 2026. Historical reported figures, not a present-day system test. No full-suite result.

The first solution was not the right one.

The inbox failed with HTTP 500. Diagnosis identified a global history conflict. The next question was which statement was justified at the level of an individual task.

DIAGNOSIS IN THE EXAMINED SNAPSHOT

42 global messages

did not establish 42 individually defective tasks.

FIRST CANDIDATE

Global warnings on individual tasks

338 selected tests passed. The warning assignment would have implied a relationship that diagnosis had not established for those tasks.

DELIBERATELY NOT ACCEPTED

LATER REPAIR

Bound the display precisely

Restore task-scoped display. Show the global notice separately. Leave strict start and approval checks unchanged.

ACCEPTED AND CONFIRMED

The meaning of the display was the criterion.

The existing task-scoped display path reported 0 conflicts in the same snapshot. That explained the different scopes of the checks; it did not prove all tasks generally error-free.

338 and 344 describe different reported test selections. They are neither added together nor treated as a comparative quality score.

What the evidence actually showed.

The report of 15 October 2026 separates technical verification, the production integration at the time and later browser confirmation. This overview preserves that limited evidence scope.

344 tests	Selected checks passed. This does not establish a fully passing repository test suite.
13 HTTP checks	Isolated checks within the reported scope. No comprehensive load or availability measurement.
Inbox HTTP 200 / 200	Direct access and the front-end web access worked; both had previously returned HTTP 500.
User confirmation	The inbox worked again in the browser. The later confirmation did not change the original technical record.

UNCHANGED BY THE REPAIR

The existing start and approval checks remained in place. The global notice had no start button. HTTP 200 did not authorise a blocked continuation.

OPEN IN THE DOCUMENTED STATE

The global continuation history was not repaired. The status update of 20 October 2026 still listed the conflict as a historical open issue. Addressing it needed a separate task.

What this case study shows about my work.

As initiator and Product Owner, I take responsibility for requirements, priorities and the substantive assessment of results. Implementation and technical analyses are carried out with AI tools.

Problem definition

Distinguish the visible usability problem from a wider technical history finding.

Assessing AI results

Consider test evidence together with the substantive meaning of the resulting display.

Prioritisation and scope

Separate a bounded restoration of usability from a distinct repair of the underlying cause.

Responsible automation

Clearly distinguish a working display, execution approvals and unresolved risks.

SOURCES AND SCOPE

Based on the internal report of 15 October and the status update of 20 October 2026. Technical figures and browser confirmation are attributed to these sources. Original exports and the runtime at the time were not independently rechecked for this account.

Internal project case, not a customer engagement. No product tests or models were run for this account. Application code and detailed internal architecture remain private.
